

NEOBANK · PRODUCT ANALYTICS

# What drives engagement, retention and churn?

Project handover — what we found, what it means for Product, and what happens next.

# What we set out to understand

From business questions to product decisions — six phases

**01–03**

## **Foundation**

Framed the problem, understood the data, defined metrics we could trust.

**04**

## **Evidence**

Tested 15 questions on engagement, retention and churn.

**05**

## **Product decisions**

Turned findings into prioritised opportunities and a clear next step.

**06**

## **Handover**

This presentation — the story and the decision, ready to use.

# Users who transact more stay engaged

Median successful transactions — engaged vs not engaged

This is the strongest recurring behavioural signal in the data.

# Users inactive in the first 30 days do worse later

Engagement rate — users with 1 or fewer transactions in first 30 days vs everyone else

~19% of users are in this group. That is the main place to investigate first.

# Premium and Crypto users are more engaged and retained

How often Premium and Crypto users are engaged or retained, compared with Standard and non-Crypto users

Numbers are rates (%). Learn from what they do — do not assume the product caused the difference.

## Notifications look useful until you account for activity

Engagement gap in percentage points — overall vs among users who already transact

Do not increase send volume. Focus on relevance and timing if you act at all.

# Country shows where churn is concentrated — not why people leave

Churn rate by country · countries with at least 100 users

UK

~41%

of all churners  
in the analysis

Largest number  
of people affected

# What we can and cannot say

## WE CAN SAY

- Activity is the strongest recurring signal
- Early low activity is a high-risk segment worth investigating
- Notifications are not a reliable lever on their own
- Country helps prioritise where to look

## WE CANNOT SAY

- That any of these cause better or worse outcomes
- That low-activity users necessarily want more transactions
- That Premium or Crypto adoption causes stronger results
- That country itself explains why users leave

# The product decision

Not “build onboarding” — validate the early low-activity problem first

1

## Validate the problem

Do these users struggle to get started — or do they simply not need the product yet?

2

## Find what Product can change

If there is friction, which product change could help them reach value sooner?

3

## Test only then

Run a controlled experiment with clear success measures and guardrails.

Discovery first. Feature investment only if the problem and mechanism hold up.

# Where to put attention next

## **01 Investigate early low activity first**

Why do many users stay almost inactive in the first 30 days?

## **02 Treat activity as the core signal**

Help users build meaningful early momentum — once the problem is validated.

## **03 Learn from Premium and Crypto users**

Understand what they do differently. Do not assume the product caused it.

## **04 Use country only to prioritise**

Start with the UK — largest number of churners. Not an explanation.

## **05 Do not increase notification volume**

The apparent benefit largely disappears once activity is considered.
